# 1 Why GenXML?

# 1.1 What is GenXML?

GenXML is a file format for exchanging data between genealogy programs. It is based on XML and defined by a XML schema. It is not intended to be used as an internal format of any genealogy programs, although it may be possible.

The idea of GenXML is that:

- It shall be easy to read by most genealogy programs.
- It shall be easy to write by most genealogy programs.
- It shall be easy to manipulate by third party programs.
- All kinds of information shall fit into one and only one place.

GenXML acknowledges the fact that there are both simple and advanced genealogy programs and that it may be used in the exchange of data both between two simple programs, between two advanced programs, from a simple program to an advanced program, and from an advanced program to a simple program.

The data exchange should be made without data loss, except in the case data is transferred from an advanced program to a simple program. All data that is impossible to import, should be written to a log file during the import. Se also chapter 5.

GenXML is mainly inspired by the theoretical Gentech Data Model (see <a href="www.gentech.org">www.gentech.org</a>) and Gedcom Future Directions, which is an unfinished replacement of Gedcom 5.5.

# 1.2 Differences Between GenXML and Gedcom

There already exists a file format for data exchange between genealogy programs. That is Gedcom, defined by the LDS church. The latest version is 5.5 and is dated 2. January 1996.

There are several problems with Gedcom 5.5:

- It is not clearly defined and is often difficult to interpret.
- There are about as many variants of Gedcom as there are programs that use it.
- It is often unclear where to put data. Almost "everything" is legal.
- Gedcom does not build upon an evidence/conclusion model.
- There is no support for data connected to the research process.
- The main purpose of Gedcom is for sending data to LDS' Ancestral File database.
- Gedcom will only have minor updates.

Compared to Gedcom, GenXML is enhanced in several ways:

- It is easier to see what version of GenXML that is used.
- The division into levels make it more easy to understand the capabilities of a program and also helps "pushing" the program developers into upgrading their program.
- GenXML is based on an evidence/conclusion model.
- There is no limit of possible kinds of events or attributes.
- GenXML includes advanced name, place and address structures.
- The main purpose of GenXML is for exchanging data between amateur genealogy programs.

# 1.3 Differences Between GenXML 1.0 and GenXML 2.0

GenXML 2.0 is designed to be simpler, easier to implement, and more flexible than GenXML 1.0. Its updated data model is a purer evidence/conclusion model.

The major differences between GenXML 1.0 and 2.0 are:

- The evidence data model has been enhanced and is now closer to the GDM evidence model while retaining compatibility with the simpler, but much more widely used, Gedcom model. As a result of this the *document* structure has been removed, and the *sourceref* and *excerpt* structures have been merged.
- The *data* substructure of the *person* structure has been replaced by an *assertion* structure which is now defined as a main structure. Some of the *assertion* substructures may be linked to more than one person.
- The association structure is renamed relationship.
- There are no longer an attribute class "residence". Instead there is now an event class "residence". The residence of a person should be considered as an event rather than an attribute, because 1) residence has no property as other attributes has, and 2) several people may share the same residence for the same period of time, as opposed to attributes that relates to only one person.
- The *children* structure (formerly substructure of *person*) is removed. The order of children is now taken care of by the *relationship* structure in the same way as other assertions.
- Both the *group* and *couple* structures have been removed. Instead events may relate to more
  than one principal person. A group or couple is from now on no more than two or more
  people participating in one or more common events.

# 2 Properties of GenXML

#### 2.1 File extension

GenXML-files should preferably have the file extension '.gml'.

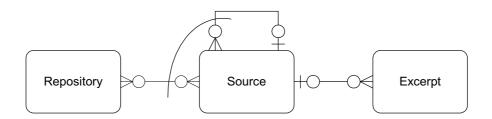

#### 2.2 Versions

The first structure in the GenXML-file is the *file* structure which tells the parser which version of GenXML the file uses. It is not a goal to make later version compatible with the current one. That would probably be a very difficult task and also limit the quality of the new version. Later versions should therefore be regarded as separate formats, like Gedcom 4.0 and 5.5 also should be regarded as separate formats.

## 2.3 Evidence and Conclutions

The GenXML format is based on an evidence/conclusion model.

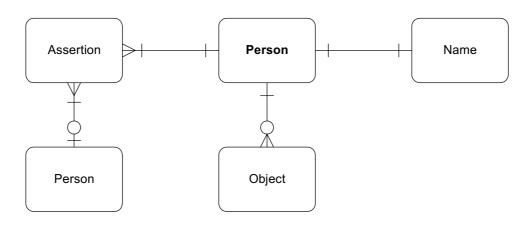

# 2.3.1 The Evidence Submodel

The main structures of the evidence part is *source*, *document* and *excerpt*. Evidence is what is found in existing (preferably primary) sources. The evidence is broken down into excerpts. The conclusions are based on these excerpts.

GenXML has a simpler evidence model than the Gentech Data Model, which uses a more generalized source entity that may be combined in an unlimited number of levels. In GenXML the number of levels are limited to three: source, document and excerpt. This will probably be more than enough for most amateur genealogy programs and it will be much simpler to implement.

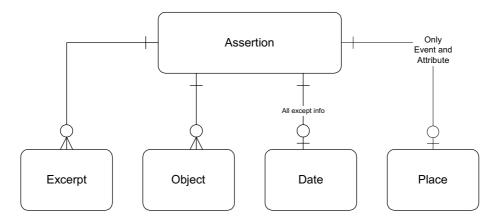

# 2.3.2 The Conclusion Submodel

The conclusions are stored as *assertions*, and all assertions are linked together through the person structure which basically represents a single individual. There are several kinds of assertions:

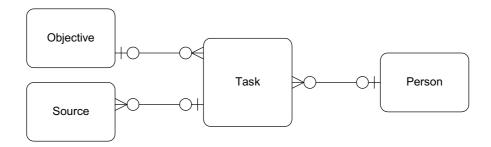

- alias
- relationship
- attribute
- event
- info

The different kinds of assertions shares many properties, although there are some differences also:

### 2.4 The Research Process

The GenXML format also includes support for the research process. This includes the *objective* and *task* structures. The Gentech Data Model also includes a project entity. This is not supported in GenXML, because the complete GenXML file is regarded as one project. This may not be satisfactory for expert systems that often have more than one user.

The *objective* structure holds one research objective. A research objective includes one or more research tasks. Each *task* may be related to one person.

Note that GenXML supports "independent" tasks – that is tasks not related to an objective. That is why *task* is a main structure and not a substructure of *objective*. This is for compatibility with programs that have only a simple todo structure. Preferably all tasks should be parts of a research objective.

## 2.5 The Note and Info Structures

The *note* structure is mainly used for short comments not meant for printing in reports. Notes meant to be printed in reports must be placed in the *info* structure (see definition in 4.5.5).

# 3 Technical Details

### 3.1 Character Set

All character sets that may be used for XML-files in general, may also be used for GenXML. That includes Unicode. However, it is not likely that most systems will support all character sets, and many systems will not support Unicode at all. It is therefore recommended that GenXML-files use ISO-8859-1. Preferably the user may choose character set when exporting GenXML.

Note that the characters '&' and '<' are reserved and must never appear in character data. They must be replaced by '&amp;' and '&lt;'. (See section 2.4 in Extensible Markup Language (XML) 1.0 (Second Edition).)

# 3.2 Definition of Datatypes

All simple datatypes, except 'ident', 'ref' and datetime are used as defined in the W3C XML Schema recommendation (see <a href="http://www.w3.org/TR/2001/REC-xmlschema-2-20010502/">http://www.w3.org/TR/2001/REC-xmlschema-2-20010502/</a>).

Datatype	Definition
base64Binary	Represents Base64-encoded arbitrary binary data as defined in section 6.8
	in http://www.w3.org/TR/xmlschema-2/#RFC2045
Boolean	Two possible values: "true" or "false".
datetime	A date on the form YYYY-MM-DD tt:mm:ss (ISO 8601). Parts of it may be
	omitted such that the following forms may be used:
	YYYY
	YYYY-MM
	YYYY-MM-DD
	YYYY-MM-DD tt:mm
	YYYY-MM-DD tt:mm:ss
ident	A 32-bit signed integer greater than 0. This is used to identify main
	structures and has to be unique for each main structure of the same type.
int	A 32-bit signed integer.
lang	Identifies the language of the tag in which it is defined. Legal values are
	language codes as defined by ISO 639, a combination of such language
	codes and country codes (ISO 3166-1) as "en-US", or IANA-
	LANGCODES (see <a href="http://www.isi.edu/in-">http://www.isi.edu/in-</a>
	notes/iana/assignments/languages/).
normalizedString	A string like the datatype string, but without any carriage return (0x0D),
	line feed (0x0A) or tab (0x09) characters. So called whitespace characters
	(tab and space) must not be repeated.
ref	A 32-bit signed integer greater than 0. Used as a pointer to main
	structures, and should be equal to the id (of type ident) of that structure.
string	A string of unlimited length.

# 4 GenXML Specifications

The following operators are used:

- ?: The field/structure must be included zero or one time.
- \*: The field/structure may be included any number of times.
- +: The field/structure must be included one or more times.

Note that other character sets than ISO-8859-1 may be used, but will not necessarily be imported by any program. ISO-8859-1 should always be supported.

All XML files starts with a header that may include information on the XML version, the character set used, the document type definition or schema used, stylesheets for visual formatting and more. This may for example look like this:

<?xml version='1.0' encoding='ISO-8859-1'?>

Definition of the main structure of a GenXML file:

```
<genxml>
  content: (file, header, repository*, source*, excerpt*, eventtype*, person*, assertion*,
  objective*, task*, total)
</genxml>
```

### Content of genxml:

Element	Type	Level
file	file structure, see section 4.1.1	1
header	header structure, see section 4.1.2	1
repository	repository structure, see section 4.1.3	3
source	source structure, see section 4.1.4	2
excerpt	excerpt structure, see section 4.1.5	2
eventtype	eventtype structure, see section 4.1.6	1
person	person structure, see section 4.1.7	1
assertion	assertion structure, see section 4.1.8	1
objective	objective structure, see section 4.1.9	4
task	task structure, see 4.1.10	3
total	total structure, see section 4.1.11	1

### 4.1 Main Structures

### 4.1.1 File

The file structure is the very first structure of the GenXML-file. This tells the parser which version of the GenXML format the file uses and at what level it is. Different versions must be regarded as separate formats. If a program only understands the 1.00-format, it should not import a 2.00-file – at least not without warning the user.

The level indicates what kind of data the importing program may expect. The file should not include data of higher levels than the given level. For example a level 2 compliant program (see section 1) using repositories, but no other data of level 3 or higher, will export a level 3 file. A level 2 file must not include any repositories.

#### Definition:

<file>

```
content: (version, level)
</file>
```

## Content of file:

Element	Type/description	Level
version	int: The GenXML-version * 100. For example is version 1.0 coded as	1
	100 and 1.1 as 110. For GenXML version 2 the value of this field	
	must always be 200.	
level	int: The highest level of which data are included. If, for example,	1
	objective structures are included in the file, then the file is a level 4	
	file, even if the exporting program is only level 2 compliant. This	
	tells the importing program what it might expect.	

### Example:

```
<file>
     <version>200</version>
     <level>2</level>
</file>
```

## 4.1.2 Header

The header structure includes information about the system that created the GenXML file, and about the owner of the database.

## Definition:

```
<header>
  content: (exportingsystem, version, exported, language?, owner?, copyright?, note?,
change?)
</header>
```

## Content of header:

Element	Type/description	Level
exportingsystem	normalizedString: Name of the exporting system.	1
version	normalizedString: Version of the exporting system	1
exported	date: The date of the export.	1
language	lang: The main language of data in this file.	2
owner	owner structure (see section 4.3.1): Information on the owner of the	N/A
	exported database.	
copyright	normalizedString: A copyright message of the exported database.	N/A
note	string: Note.	N/A
change	datetime: The date and time of the last change of this database.	N/A

### Example:

## 4.1.3 Repository

The repository structure represents a repository of sources, like a library or a public record office.

### Definition:

```
<repository>
  attributes: (id, lang?)
  content: (name, address?, email?, uri?, note?, change?)
</repository>
```

# Attributes of repository:

Element	Type/description	Level
id	ident: Unique identifier	3
lang	lang: The language of the repository information.	3

# Content of repository:

Element	Type/description	Level
name	normalizedString: The name of the repository.	3
address	address structure (see section 4.2.4): The address of the repository.	3
email	normalizedString: Email address of the repository.	3
uri	normalizedString: World wide web homepage of the repository.	3
note	stringlang structure (see section 4.2.1): Note.	3
change	datetime: The date and time of the last change of this repository	N/A
	information.	

# Example:

### 4.1.4 Source

The source structure represents a book, a collection of documents, or similar. It may be printed, hand-written, in electronic form, or on microfilm/-fiche.

### Definition:

## Attributes of source:

Element	Type/description	Level
id	ident: Unique identifier	2
class	"series": This is a series consisting of more than one volumes. It	
	may also be a periodical.	
	"book": This is a single book or a single volume of a series.	
	"issue": This is an issue of a periodical, for example a magazine.	
	"article": This is an article, in for example a magazine.	

		1
	"part": This is a part of a book, consisting of more than one chapter	
	or documents.	
	"chapter": This is a chapter.	
	"document": This is a document, such as a birth certificate, a	
	census entry, a church register entry, or an inscription like a	
	tombstone.	
	"section": This is a part of a chapter.	
	"excerpt": This is a single excerpt, consisting of one or a few	
	sentences.	
kind	"original": This is an original source.	4
	"reprint": This is a reprint of the original source.	4
	"copy": This source is a copy or transcript of the original source.	4
	"unknown" (default): It is not known if this source is an original or	2
	a copy.	
media	"printed": This is a printed source.	4
	"handwritten": This source is handwritten.	4
	"fiche": This source is published on microfiche.	4
	"microfilm": This source is published on microfilm.	4
	"photo": This source exists as a photography.	4
	"inscription": This source is an inscription, for example on a	4
	tombstone.	
	"digital": This source exists as a digital file.	4
	"other": This source exists on some other kind of media than the	4
	ones described above.	
	"unknown" (default): The media of this source is unknown.	2
lang	lang: The language of the source.	3

# Content of source:

Element	Type/description	Level
author	normalizedString: The name of the source's author or editor.	2
title	normalizedString: The complete title of the source.	2
shorttitle	normalizedString: A short version of the title.	2
published	normalizedString: Publication facts such as where the source was	2
	published, the name of the publisher, and the year it was	
	published.	
isbn	normalizedString: International Standard Book Number. A 10-digit	4
	number which identifies any published book or edition.	
issn	normalizedString: International Standard Serial Number. A &digit	4
	number which identifies any periodicals.	
repositoryref	repositoryref substructure (see section 4.6.1): Includes a pointer to	3
	a repository structure.	
sourceref	ref: Pointer to a 'higher' source record representing a source of	
	which this source is a part. For example this source may represent	
	an specific volume, while the 'higher' source represents the entre	
	series.	
text	string: Text from the source.	2
object	object structure (see section 4.2.3): An object related to the	4
	document. (For example a picture of the document.)	
note	stringlang structure (see section 4.2.1): Note.	2
change	datetime: The date and time of the last change of this source	N/A
	information.	

# 4.1.5 Excerpt

The excerpt structure represents a single excerpt (like "John was the third son of Robert" or "John was 64 years old in 1759") extracted from a source.

# Definition:

```
<excerpt>
  attributes: (id, lang?)
  content: (text?, quality?, page?, sourceid, note?, change?)
</excerpt>
```

# Attributes of excerpt:

Element	Type/description	Level
id	ident: Unique identifier	2
lang	lang: The language of the excerpt.	4

## Content of excerpt:

Element	Type/description	Level
text	string: Text extracted from the referred document.	4
quality	an integer between 0 and 100: This is the quality of the document	3
	or data from the referred source, in percents of reliability. If this is	
	not present, the quality must be regarded as unknown	
page	normalizedString: A short description of where in the source the	2
	referred data exist.	
sourceid	ref: Pointer to a source structure.	2
note	stringlang structure (see section 4.2.1): Note.	4
change	datetime: The date and time of the last change of this excerpt	N/A
	information.	

The conversion between "quality" and Gedcom QUAY is recommended to be done according to the following table:

Gedcom QUAY-value	GenXML "quality"
0 – unreliable evidence	0-49%
1 – questionable reliability of	50-79%
evidence	
2 – secondary evidence	80-94%
3 – primary evidence	95-100%

# 4.1.6 EventType

The *eventtype* represents a certain event type (such as marriage, birth, retirement), user defined or application defined.

Note that the class is always a noun while the description would typically be a verb (birth – born, baptism – baptized).

The description field makes event types language dependant. It may seem a drawback that the event types can't easily be translated from a language to another. But event types may be quite different in different cultures, and an automatic translation may not retain the correct meaning. It is therefore important to understand that the event types is a part of the database as well as other genealogical data, and the database can only be translated by a qualified person.

#### Definition:

```
<eventtype>
  attributes: ( id, class, lang? )
  content: ( description, gedcomtag?, roles?, note? )
</eventtype>
```

# Attributes of eventtype:

Element	Type/description	Level
id	ident: Unique eventtype identifier.	1
class	"annulment": The annulment of a marriage.	3
	"baptism": Any kind of baptism or similar events.	2
	"birth": The birth of the person.	1
	"blessing": Any kind of blessing or similar events.	3
	"burial": Any kind of burial (for example funeral or interment).	2
	"census": Any kind of events dealing with the counting of people.	3
	"confirmation": Any kind of confirmation or similar events	3
	regardless of religion.	
	"coronation": Any kind of coronation or similar events.	3
	"cremation": The cremation of a person.	3
	"death": The death of a person.	1
	"discharge": The event of leaving the army.	3
	"divfiling": The event of filing for a divorceby a spouse.	3
	"divorce": The event of dissolving a marriage.	2
	"election": The event of being elected or similar.	3
	"emigration": The event of leaving the place where one live.	3
	"enlistment": Any kind of enlistment to the army, or similar	3
	events.	
	"graduation": The event of graduating from a school or university,	3
	or similar.	
	"immigration": The event of entering a new locality with the	3
	intention of residing there.	
	"internment": The event of being interned, or similar.	3
	"marriage": The event of uniting two persons in marriage or similar union.	1
	"naturalization": The event of obtaining citizenship in a city or a	3
	country, or similar events.	
	"ordination": The event of receiving authority to act in religious	3
	matters, or similar events.	
	"residence": The address or place where one or more persons	3
	live(d).	
	"retirement": Any kind of retirement.	3
	"other": Any other kind of events.	3
lang	lang: The language of the eventtype information.	4

# Content of eventtype:

Element	Type/description	Level
description	normstringlang structure (see section 4.2.2): Short description of	1
	the event type.	
gedcomtag	token (Default is "EVEN"): The GEDCOM 5.5-tag of this event	3
	type.	
roles	int (Default is "1"): The maximum number of principal roles in this	3
	event type. If this value is set to "0", it means that events of this	
	type may have an unlimited number of principal roles. Note that	
	GenXML can't guarantee that no events of this type has more	
	principal participants than specified here.	
note	stringlang structure (see section 4.2.1): Note.	4

# Example:

#### 4.1.7 Person

The *person* structure represents a single individual. If, however, there are two persons, each with their own data, that may be the same individual, there may be created a third *person* that, through the *subpersons* substructure, combines the two persons into one. If it is certain that the two person records really represents the same individual, they should be merged into one instead of using the *subpersons* structure. Note that no data except a name may be connected to a *person* record using the *subpersons* structure.

### Definition:

```
<person>
  attributes: (id, sex, lang?)
  content: (name, (subpersons? | (excerptref*, object*) ), note?, change?)
</person>
```

# Attributes of person:

Element	Type/description	Level
id	ident: Unique identifier	1
sex	"male": This person is a man.	1
	"female": This person is a woman.	1
	"unknown": The sex of this person is unknown.	3
lang	lang: The language of the person information.	3

## Content of person:

Element	Type/description	Level
name	name structure (see section 4.2.6): Name of the person. This may be a normalized version of the persons name. The name as found in sources is stored in the alias record.	1
subpersons	subpersons structure (see section 4.4.1): A structure used for combining to persons into one.	4
excerptref	id: Pointer to an excerpt structure holding information which source and where in that source information on this person was found.	2
object	object structure (see section 4.2.3): External files related to this person.	3
note	stringlang structure (see section 4.2.1): Notes made by the researcher that does not fit in anywhere else. (The document and excerpt structures are preferred.) Comments that are meant to be printed on reports (for example the life of the person) should be stored in the info structure.	2
change	datetime: The date and time of the last change of this person information.	N/A

### 4.1.8 Assertion

The *assertion* represents a piece of conclusional data for a person, such as the birth date, hair color or relationships.

## Definition:

#### Attributes of assertion:

Element	Type/description	Level
id	ident: Unique assertion identifier.	1
datatype	"public" (default): Indicates "public" information that will be	4
	printed in reports and exported.	
	"family": The data is public to family members only.	4
	"immfamily": The data is public to the immediate family only.	4
	"private": Indicates private or confidential information that will	4
	not normally be printed in reports or exported.	
	"info": Indicates information that will normally not be printed in	4
	reports, not because it is private, but because it is mostly of interest	
	to the researcher only.	
lang	lang: The language of the assertion information.	3

#### Content of assertion:

Element	Type/description	Level
alias	alias structure (see section 4.5.1): The assertion is a name alias.	
relationship	relationship structure (see section 4.5.2): The assertion is a	1
	relationship (a parent-child relationship or other relationship).	
attribute	attribute structure (see section 4.5.3): The assertion represents an	1
	attribute of the associated person(s).	
event	event structure (see section 4.5.4): The assertion represents an event	1
	(like birth, death, marriage or divorce).	
info	stringlang structure (see section 4.2.1): This is a string that may	1
	hold general information about a person that does not fit into any	
	of the other assertion structures.	
excerptref	id: Pointer to an excerpt structure on which this assertion is based.	2
assertionref	id: Pointer to an assertion on which this æsertion is based. An	
	assertion may be based on two other assertions instead of an	
	excerpt.	
object	object structure (see 4.2.3): Objects related to this couple.	3
note	stringlang structure (see section 4.2.1): Note.	2
change	datetime: The date and time of the last change of this couple	N/A
	information.	

## 4.1.9 Objective

The objective structure represents a research objective. A research objective consists of one or more research tasks (see section 4.1.10). The research objective is split into one task for each affected person, couple or group.

Note that the research objective may be seen as having a status, like the research task. The objective's status equals the lowest status of its tasks. This may easily be calculated by a program. The research objective is not completed until all of its tasks are completed.

The task substructure should be regarded as a substructure of the objective structure. But since the task structure is a level 3 structure and objective is a level 4 structure, also the task structure is implemented as a main structure.

## Definition:

```
<objective>
  attributes: (id, lang?)
  content: (title, problem, solution, priority?, created?, change?)
</objective>
```

# Attributes of objective:

Element	Type/description	Level
id	ident: Unique identifier	4
lang	lang: The language of the research objective information.	4

# Content of objective:

Element	Type/description	Level
title	string: Short description of the research objective.	4
problem	string: Complete description of the research objective. Note that	4
	details regarding a single group, couple or person should be stored	
	in the corresponding task structure.	
solution	string: Complete description of the solution of the problem. Note	4
	that details regarding a single group, couple or person should be	
	stored in a corresponding task structure.	
priority	"low": The research objective has low priority.	4
	"medium": The research objective has medium priority.	4
	"high": The research objective has high priority.	4
created	datetime: The date of the creation of the research objective.	4
change	datetime: The date and time of the last change of this research	N/A
-	objective.	

# 4.1.10 Task

The task structure represents a research task. A research task may be related to a specific group, couple or person, and to one or more sources. It may (and should) also be part of a research objective.

## Definition:

```
<task>
    attribute: (id, lang?)
    content: (title, problem, solution?, objective?, person?, source?, status, statusdate?, change?)
</task>
```

# Attributes of task:

Element	Type/description	Level
id	ident: Unique identifier	3
lang	lang: The language of the research task information.	3

# Content of task:

Element	Type/description	Level
title	string: Short description of the problem.	3
problem	string: Complete description of the problem and what need to be	3
	done.	
solution	string: Description of the solution. This should be used for	3
	archiving purposes.	
objective	ref: Pointer to a objective structure. The task should always be a	4
	part of an objective if the objective structure is supported by the	
	exporting program.	
person	ref: Pointer to a person structure.	3
source	ref: Pointer to the source that is to be searched.	3
status	"new": This task is registered, but work is not started.	3
	"analysis": The work on this task has started.	3
	"finished": The work on this task is finished.	3
	"updated": The database has been updated with the results from	3
	the work on this task, and the case is dosed.	

	"rejected": The task is rejected and will not be executed.	3
statusdate	datetime: The date of the last status change. This value is system	3
	generated and not typed in by the user.	
change	datetime: The date and time of the last change of thisresearch task.	N/A

# 4.1.11 Total

The TOTAL structure is always the last one in the file and should always be included. The purpose is to tell the importing program how many structures that should have been imported.

### Definition:

```
<total>
content: (repositories, sources, excerpts, eventtypes, attributetypes, persons, assertions, objectives, tasks)
</total>
```

### Content of total:

Element	Type/description	Level
repositories	int: The total number of repository structures in the file.	1
sources	int: The total number of source structures in the file.	1
excerpts	int: The total number of excerpt structures in the file.	1
eventtypes	int: The total number of eventtype structures in the file.	1
persons	int: The total number of person structures in the file.	1
assertions	int: The total number of assertion structures in the file.	1
objectives	int: The total number of objective structures in the file.	1
tasks	int: The total number of task structures in the file.	1

## Example:

```
<total>
  <repositories>1</repositories>
  <sources>4</sources>
  <excerpts>0</excerpts>
  <eventtypes>12</eventtypes>
  <persons>124</persons>
  <assertions>49</assertions>
  <objectives>0</objectives>
  <tasks>0</tasks>
</total>
```

# 4.2 General Substructures

# 4.2.1 Stringlang

General string with language attribute.

### Definition:

```
<[stringlang]>
attribute: (lang)
data: string
</[stringlang]>
```

Note that the name of the structure may vary.

# Attribute of note:

Element	Type/description	Level
---------	------------------	-------

lang	lang: The language of the note.	4
------	---------------------------------	---

# 4.2.2 Normstringlang

General normalized string with language attribute.

## Definition:

```
<[normstringlang]>
attribute: (lang)
data: normalizedString
</[normstringlang]>
```

Note that the name of the structure may vary.

### Attribute of note:

Element	Type/description	Level
lang	lang: The language of the note.	4

## 4.2.3 Object

Objects represents a file. An object may be included as a reference to an external file (using *externalfile*) or completely included in the GenXML file (using *originalfile* and *data*). If *object* is used as a reference to an external file, that external file should be present in the same folder as the GenXML-file

# Definition:

```
<object>
  attribute: (lang?)
  content: ( (externalfile | (originalfile, bin) ), title, note?)
</object>
```

## Attribute of object:

Element	Type/description	Level
lang	lang: The language of the object information (and content if	4
	applicable).	

# Content of object:

Element	Type/description	Level
externalfile	token: The name of the external file. No directory information may	3
	be included. All files should be exported to (or imported from) the	
	same directory.	
originalfile	token: The name of the original file.	3
bin	base64Binary: The object data base64-encoded.	3
title	normalizedString: Short description of the object.	3
note	string: Note.	3

## 4.2.4 Address

The address structure represents an postal address of something, someone or where something happened. It is formatted as it would be for example on a mailing label.

The tag <lf/> is used to separate lines. Note that addresses often are limited to four lines (excluding the addressee). Of these, the third line is usually used for the city-name and postal code, while the fourth line is used for the name of the country. If, four example, the second line is not used, it should still be included (by an extra <lf/>, se the examples). There may or may not be an <lf/> after the last line. Importing programs should be aware though, that in some countries the address is written "upside-down". It that cases the country will be put in the first line, the city in the second etc.

An importing program that is not level 4 compliant, will usually ignore the tp-attribute.

### Definition:

```
<address>
attributes: (lang?)
content: ( (ap | lf)*, phone?, fax?)
</address>
```

### Attributes of address:

Element	Type/description	Level
lang	lang: The language in which the address is written.	4

## Content of address:

Element	Type/description	Level
ap	normalizedString: Address part. Includes the optional attribute <i>tp</i>	1/4
	(see definition below).	
lf	no data: Line feed. Indicates that the following apfields belong to	1
	the next address line.	
phone	normalizedString: Phone number at this address.	2
fax	normalizedString: Fax number at this address.	3

Possible values of the *tp* attribute of the *ap* field:

Element	Type/description	Level
tp	"name": The address part refers to the name of the house. This is	4
	only used if the house have a name and it is used as a part of the	
	postal address.	
	"street": The address part refers to a street name.	4
	"number": The address part refers to the number of the house. This	4
	is usually not included without the name of the street.	
	"district": The address part refers to the local district. This is	4
	mainly used when there is no street name.	
	"pobox": The address part refers to a postal office box. Both the	4
	number of P. O. box and the description of it should be included.	
	(For example "P. O. Box 57".)	
	"pcode": The postal code or ZIP code.	4
	"city": The address part refers to a town or city, or it may be the	4
	name of the nearest post office.	
	"country": The address part refers to a country.	4
	"state": The address part refers to a state name. This is used only in	4
	USA, Canada and Australia.	
	"other": The address part is of some other kind than those above.	4
	"unknown" (default): The address part is of an unknown type, or	1
	the exporting program does not support the above address part	
	descriptions.	

### Examples of level 1 addresses:

<address>

```
<ap>Øvre Strandgate 75</ap><lf/><ap>4300 Stavanger</ap><lf/>
<ap>Norway</ap>
</address>
<address>
  <ap>50 East North Temple Street</ap><lf/>
<ap>Salt Lake City, UT 84150</ap><lf/>
<ap>USA</ap>
</address></address></ap></address></ap></ar>
```

## Examples of level 4 addresses:

```
<address>
    <ap tp="name">Madsegården</ap><lf/>
    <ap tp="district">Brueland</ap><lf/>
    <ap tp="pcode">4300</ap>
    <ap tp="city">Sandnes</ap><lf/>
    <ap tp="country">Norway</ap>
</address>
```

## 4.2.5 Place

The place structure represents a place where some event happened. It is not intended for postal addresses.

## Definition:

```
<place>
  attribute: (lang?)
  content: ( prefix?, pnp+, date?, coords? )
</place>
```

# Attribute of place:

Element	Type/description	Level
lang	lang: The language in which the place name is written.	4

Content of place:

Element	Type/description	Level
prefix	normalizedString: Prefix used when printing place names, like	4
	"in", "at" or "near".	
pnp	normalizedString: Place name part. Includes the optional attribute	1/4
	<i>tp</i> (see definition below).	
date	date structure (see section 4.2.8): The period when this place name	4
	was valid.	
coords	coords structure (see 4.2.7): The geographical coordinates of the	4
	place.	

Possible values of the *tp* attribute of the *pnp* field:

Element	Type/description	Level
tp	"continent": The place name part refers to a continent or part of the	4
	world.	
	"country": The place name part refers to a country.	4
	"state": The place name part refers to a part of a country which are	4
	partly independent, like a state in USA or a greater principality.	
	"county": The place name part refers to a county or province, a	4
	part of a country or state, or a lesser principality, with its own	
	authorities.	
	"town": The place name part refers to a town or city.	4
	"muni": The place name part refers to a municipality.	4

"citypart": The place name part refers to a part of a town or city.	4
"building": The place name part refers to a building or a group of	4
buildings, like a church or monastery.	
"diocese": The place name part refers to an ecclesiastical district	4
under the jurisdiction of a bishop.	
"deanery": The place name part refers to a district under the	4
jurisdiction of a dean, part of a diocese.	
"parish": The place name part refers to an ecclesiastical district	4
with its own church.	
"farm": The place name part refers to a farm or estate.	4
"ocean": The place name part refers to an ocean or sea of salt	4
water.	
"lake": The place name part refers to a lake.	4
"mountain": The place name part refers to a mountain.	4
"cemetery": The place name part refers to a cemetery.	4
"other": The place name part refers to an other kind of	4
geographical area or jurisdiction than the one above.	
"unknown" (default): The place name part is of an unknown type	1
or the exporting program does not support the above place name	
 part descriptions.	

## Example of level 1 place:

```
<place>
    <pnp>Balquholly Castle</pnp><pnp>Aberdeenshire</pnp><pnp>Scotland</pnp>
</place>
```

# Example of level 4 place:

#### 4.2.6 Name

The name structure records the name by which the user wants to identify the person and not necessarily as found in a source. Names as found in a source is stored in the alias structure (see section 4.5.1).

The name is split into name parts. Note that a name part may consist of more than one name. For example

Name parts like articles and prepositions may be included with the name part it belongs to, or it may be regarded as a separate name part using tp="art". This should somehow be decided by the user who registers the name. One simple rule to decide this is how the user wants the name sorted. If you want the name "Godske von Ahlefeld" sorted by surname as "von Ahlefeld, Godske" then it should be recorded as

```
<np tp="givn">Godske</np>
<np tp="surn">von Ahlefeld</np>
```

If you want it sorted by surname as "Ahlefeld, Godske von" it should be recorded as

```
<np tp="givn">Godske</np>
<np tp="art">von</np>
```

```
<np tp="surn">Ahlefeld</np>
```

# Definition:

<name>
 attribute: (lang?)
 content: (np+)
</name>

# Attribute of name:

Element	Type/description	Level
lang	lang: The language in which the name is written.	4

# Content of name:

Element	Type/description	Level
np	normalizedString: Name part. Requires the attribute tp (see below).	1

Possible values of the *tp* attribute of the *np* field:

Element	Type/description	Level
tp	"cogn": A cognomen or nickname given in addition to the other	4
	name(s) (like "the great" or "Germanicus").	
	"surn": Surname. The surname, family name, clan name or similar	1
	inherited name of the person. Each person has normally only one	
	surname. If the name is a surname, but not <i>the</i> surname of the	
	person, the correct description is "midl" and not "surn". Also note	
	that because a son has the same name as his father does not	
	necessarily mean that the name is automatically inherited and may	
	therefore not be a true surname but a cognomen, occupation name,	
	locality name or similar.	
	"pref": Title or prefix that is normally included as a part of the name, like "Sir".	4
	"givn": Given name. The given name of the person. The person	4
	may have several of these.	
	"reln": Religious name. This is a name the person is given, or has	4
	taken, as a religious name and not as a normal given name.	
	"nick": A nickname substituting the given name (like "Bill" instead	4
	of "William").	
	"patr": Patronymic name. A name created from the person's	4
	father's name.	
	"matr": Matronymic name. A name created from the person's	4
	mother's name.	
	"tekn": Teknonymic name. A name created from one of the	4
	person's children's name.	
	"art": Article. ("de", "von", "of" or similar)	4
	"occn": Occupation name.	4
	"locn": Locality name.	4
	"midl": Middle name. Any kind of family name that is not the	4
	surname of this person, like the maiden name of a married woman.	
	A middle name is a family name that may be the inheritable	
	surname for other persons or families, but not for this person. This	
	is not middle name in the American sense of the term. The	
	Americans don't have middle names in the GenXML sense. If a	
	person has two given names they should be coded as two "givn"	
	and not as one "givn" and one "midl".	
	"sufx": Suffix. ("sr.", "jr." or similar.)	4
	"oth": A name part of some other type than the ones above.	4
	"unkw": A name part which type is unknown.	1

### Examples of level 1 names:

# Examples of level 4 names:

```
<np tp="givn">Billy</np>
   <np tp="cogn">the Kid</np>
</name>
<name>
  <np tp="givn">Godske</np>
   <np tp="art">von</np>
  <np tp="surn">Ahlefeld</np>
  <np tp="art">til</np>
  <np tp="locn">Bosse</np>
   <np tp="art">og</np>
   <np tp="locn">Lindau</np>
</name>
<name>
  <np tp="givn">Gaius</np>
   <np tp="surn">Julius</np>
  <np tp="cogn">Caesar</np>
</name>
<name>
  <np tp="nick">Bill</np>
   <np tp="surn">Clinton</np>
</name>
```

Note that although many of the Roman cognomens were inherited, they were not true surnames. They were not necessarily inherited by all family members. We may often see that the oldest son inherits the cognomen of his father, while the younger sons get a different cognomen.

#### 4.2.7 Coords

This structure holds the geographical coordinates of a place name.

#### Definition:

```
<coords>
  content: (lo, la)
</coords>
```

## Content of coords:

Element	Type/description	Level
lo	dDD, dDDMM or dDDMMSS: Longitude of the place, in degrees	4
	(DD), minutes (MM) and seconds (SS). The prefix (d) must be	
	either "W" or "E".	
la	dDD, dDDMM or dDDMMSS: Latitude of the place, in degrees	4
	(DD), minutes (MM) and seconds (SS). The prefix (d) must be	
	either "N" or "S".	

### 4.2.8 Date

The date structure represents a specific date (known or unknown) when something happened, or it may represent a period of time.

Note that the original date phrase belongs in the *excerpt* structure. The *date* structure holds the dates that are to be presented in reports.

### Definition:

```
<date>
  content: (exact | (begin, end) | from | to | (from, to) | text)
</date>
```

#### Content of date:

Element	Type/description	Level
exact	simpledate structure (see 4.2.9): An exact date, known or unknown.	1
begin	simpledate structure (see 4.2.9): 'begin' and 'end' represents an unknown date in a known date range. This kind of dating will normally be written as "between <begin> and <end>" in ordinary text.</end></begin>	3
end	simpledate structure (see 4.2.9): End date of a date range. See 'begin'.	3
from	simpledate structure (see 4.2.9): 'from' and 'to' represents periods of time. They may be used alone or together.	2
to	simpledate structure (see 4.2.9): End date of date period. See 'from'.	2
text	normalizedString: Any date written as free-form text. Other fields should be used if possible.	2

# Examples:

# 4.2.9 Simpledate

Simpledate represents a single date.

### Definition:

```
<[simpledate]>
  attributes: (cal?, mod?, era?)
  data: (date)
</[simpledate]>
```

Note that the name of the structure may vary.

# Attributes of simpledate:

Element	Type/description	Level
cal	"chinese": It is a date in the Chinese calendar.	3
	"coptic": It is a date in the Coptic or Ethiopian calendar.	3
	"french": It is a date in the French revolutionary calendar.	3
	"gregorian": It is a date in the Gregorian calendar.	1
	"hebrew": It is a date in the Jewish calendar.	3
	"indian": It is a date in the Indian calendar.	3
	"islamic": It is a date in the Islamic calendar.	3
	"julian": It is a date in the Julian calendar.	3
	"unknown" (default): Unknown calendar.	3
mod	"about": The exact date is close to the given date.	2
	"after": The exact date is after the given date.	2
	"before": The exact date is before the given date.	2
	"estimated": The exact date is estimated as specified.	2
era	"after" (default) or "before": Indicates if the date is after or before	3
	the start of this era. Note that "before" isonly defined for the Julian	
	calendar (equals "before Christ").	

# Data of simpledate:

Element	Type/description	Level
<b>Element</b> date	Type/description  This format of this field is an extension of ISO 8601 and the general format is: YYYY[/ZZ][-MM[-DD[ tt:mm[:ss]]]]  The date is represented by the year (0000 or greater) and the alternate year (0000 or greater), the month (0 – 12 or 13 depending on the calendar used), and the day (0 – 31). Zero indicates that that part of the date is unknown. The number of digits is fixed. The alternate year (ZZ) is optional and is only used to show the possible date alternatives for dates using the Julian calendar. For	1/3/4
	example 1532/33-02-16 indicates that the date was in the year 1532 because New Year's Day was 25. March, but would have been in the year 1533 if New Year's Day was 1. January. tt:mm:ss represents the time (times, minutes and seconds), ranging from 00:00:00 to 24:00:00. Note that 2002-04-12 00:00:00 equals 2002-04-11 24:00:00. Since the time 00:00:00 does have a meaning, the time should be omitted if it is unknown.  The number of digits for each part is always fixed, i. e. 3 July 1957 should be represented as 1957-07-03 and not 1957-7-3.	

Examples: See the date structure.

# 4.3 Substructures of the Header Structure

# 4.3.1 Owner

The owner substructure contains information on the owner of the exported database.

## Definition:

```
<owner>
  content: (name, address?, phone?, email?, uri?)
</owner>
```

# Content of owner:

Element	Туре	Level
name	normalizedString: The name of the owner.	N/A
address	address structure (see section 4.2.4): The address of the owner.	N/A
email	normalizedString: Email address of the owner.	N/A
uri	normalizedString: Homepage of the owner.	N/A

# 4.4 Substructures of the Person Structure

# 4.4.1 Subpersons

The *subpersons* structure is used for combining two (and only two) persons that probably (but not necessarily) were the same individual. For more information, see the *person* structure.

## Definition:

```
<subpersons>
  attributes: (probability?)
  content: (personref, personref)
</subpersons>
```

### Attributes of subperson:

Element	Type/description	Level
probability	int: The probability (in %) of the referred persons being one and	4
	the same.	

## Content of subperson:

Element	Type/description	Level
personref	ref: Pointer to a person.	4
note	stringlang (see section 4.2.1): A note. This is the description of the	4
	assumption made.	

### Example:

```
<subperson probability="50">
   <personref>1743</personref>
   <personref>1746</personref>
</subperson>
```

# 4.5 Substructures of the Assertion Structure

#### 4.5.1 Alias

The alias structure stores a name of a person as found in a source. The user may want to normalize it, though, and refer to an *excerpt* with the exact spelling.

### Definition:

```
<alias>
  attribute: ( negative? )
  content: ( name, personref, date? )
</alias>
```

## Attributes of alias:

Element Type/description	Level
--------------------------	-------

negative	boolean (Default is "false"): Indicates "negative" information. If	4
	set to "true", this name was not used by the referred person.	

## Content of alias:

Element	Type/description	Level
name	name structure (see section 4.2.6): The name of the person as	2
	recorded in the referred source.	
personref	personref structure (see section 4.5.6): Pointer to the owner of this	2
	name.	
date	date structure (see section 4.2.8): The date or period when this	3
	name was used.	

# 4.5.2 Relationship

The relationship structure represents a parent-child relationship. The father-child and mother-child relationships may optionally be combined into a single relationship.

# Definition:

```
<relationship>
  attribute: ( pref?, negative? )
  content: ( relation, ( father | mother | ( father, mother ) )?, child, date? )
</relationship>
```

# Attributes of relationship:

Element	Type/description	Level
pref	boolean: (Default is "true".) States if this is the preferred structure	2/3
	of all association structures of the same class ("true"). If this	
	attribute is not set for any structures of the class, the first one may	
	be regarded as the preferred one. If more than one association of	
	the same class have this attribute set to "true", the first of these	
	may be regarded as the preferred one.	
negative	boolean (Default is "false"): Indicates "negative" information.	4

### Content of relationship:

Element	Type/description	Level
relation	"biological": The relationship is biological.	1
	"adoptive": The relationship is through adoption.	3
	"foster": The relationship is through foster-parents.	3
	"other": The relation or association is of some other kind.	3
father	personref structure (see section 4.5.6): ID-number of the father in	1
	this relationship.	
mother	personref structure (see section 4.5.6): ID-number of the mother in	1
	this relationship.	
child	personref structure (see section 4.5.6): ID-number of the child in	1
	this relationship.	
date	date structure (see section 4.2.8): The date when this association	3
	was established, or the period during which this association was	
	valid. For example this may be the date of an adoption. There is no	
	point in storing the birth date of a person here.	

## 4.5.3 Attribute

The attribute structure represents an attribute or characteristic of a person. As opposed to events, attributes typically take place over a period of time.

Like events, attributes are of the same type only when both class and description are identical. If the description is omitted, the importing application may choose a description based on the class.

Attribute corresponds to the Characteristic entity of GDM.

When compared to GEDCOM 5.5's the class (textclass, numberclass or flagclass) corresponds to the attribute tag (for example EDUC, NCHI or OCCU), while *description* corresponds to the TYPE tag of the Event\_Detail structure.

# Definition:

```
<attribute>
    attribute: ( pref?, negative? )
    content: ( description?, ( ( textclass, text ) | ( numberclass, number, modifier? ) | flagclass ),
        personref, date?, place? )
</attribute>
```

## Attributes of attribute:

Element	Type/description	Level
pref	boolean: (Default is "true".) States if this is the preferred structure	2/3
	of all attribute structures of the same kind ("true"). If this attribute	
	is not set for any structures of the kind, the first one may be	
	regarded as the preferred one. If more than one attribute of the	
	same kind have this attribute set to "true", the first of these may be	
	regarded as the preferred one.	
negative	boolean (Default is "false"): Indicates "negative" information.	4

#### Content of attribute:

Element	Type/description	Level
description	normstringlang (see section 4.2.2): Short description of the kind of attribute.	3
textclass	"caste": The caste to which this person belonged.	3
	"education": Education. Note that the graduation is an event.	3
	"email": Email address.	3
	"idnumber": Any kind of national ID number, like social security number.	3
	"language": The language spoken by the person (for example native language).	3
	"nationality": The nationality of the person.	3
	"physical": Any kind of physical description of the person.	3
	"property": Property owned by the person.	3
	"religion": The religion with which the person was affiliated.	3
	"residence": A place where the person lived for some time.	3
	"title": A title, like a nobility title or similar.	3
	"work": Occupation.	1
	"other": Any other kind of text-based attribute.	3
text	normstringlang (see section 4.2.2): The details of the attribute.	1
numberclass	"children": The total number of children, not the calculated sum of registered children.	
	"marriages": The total number of marriages, not the calculated sum of registered marriages.	
	"other": Any other kind of number-based attribute.	
number	int: The details of this attribute.	
modifier	"exact" (default): The number specified is exact.	
	"greater": The number is greater than specified.	
	"less": The number is less than specified.	
flagclass	"ancestor": This person is an ancestor of some unspecified person.	

	"descendant": This person is a descendant of some unspecified	
	person.	
	"living": This person is still living, or was living at the specified	
	date.	
	"other": Any other kind of flag-based attribute.	
personref	personref structure (see section 4.5.6): ID-number of the person to	1
	which this attribute apply.	
date	date (see section 4.2.8): The date or period during which the	3
	attribute existed or was valid.	
place	place (see section 4.2.5): The place where the attribute was (if any).	3

### **Examples:**

```
<!--Person with id=57 was a fisherman-->
<attribute>
  <description>occupation</description>
  <textclass>work</textclass>
  <text>fisherman</text>
  <personref>57</personref>
</attribute>
<!--Person with id=193 had at least 7 children-->
   <numberclass>children</numberclass>
   <number>6</number>
   <modifier>greater</modifier>
   <personref>193</personref>
</attribute>
<!--Person with id=20 was not living 4. December 1964-->
<attribute negative="true">
  <flagclass>living</flagclass>
  <personref>20</personref>
  <date><exact>1964-12-04</exact></date>
</attribute>
```

#### 4.5.4 Event

The event structure represents an event in the life of one or more persons. An event is something that happened at a certain moment – a certain day.

The event may include many participants that have different roles in the event. However one must distinguish between principal participants in the event and participants that have a subordinate role. In a christening event, the person that is born is the principal participant. The godfather, godmother, priest, and all other participants have a subordinate role. In a wedding there are two principal participants: the bride and the groom. In some events, for example the invasion of Normandy 5. June 1944, there are a very large number of principal participants. (In such "group" - events, talking of subordinate participants has little meaning.)

All events have at least one principal participant. However in some cases the principal participant may be unknown. Therefore the principal field is not mandatory.

Note that although the parents of a child do have a subordinate role in the birth event of the child, the parent-child relationship should not be recorded using this mechanism. Instead use the relationship structure (see section 4.5.2).

#### Definition:

```
<event>
  attribute: ( type, pref?, negative? )
```

```
content: ( principal*, subordinate*, date?, place? )
</event>
```

## Attributes of event:

Element	Type/description	Level
type	id: ID-number of the event type (see section 4.1.6) of which this	1
	event is an instance.	
pref	boolean: (Default is "true".) States if this is the preferred structure	2/3
	of all personevent structures of the same kind ("true"). If this	
	attribute is not set for any structures of the kind, the first one may	
	be regarded as the preferred one. If more than one structures of the	
	same kind have this attribute set to "true", the first of these may be	
	regarded as the preferred one.	
negative	boolean (Default is "false"): Indicates "negative" information.	4

### Content of event:

Element	Type/description	Level
principal	personrefrole structure (see section 4.5.7): Pointer to the principal	1
	person of this event	
subordinate	personrefrole structure (see section Feil! Fant ikke	4
	referansekilden.): Pointer to a person that has a subordinate role	
	in this event.	
date	date structure (see section 4.2.8): The date when the event	1
	happened.	
place	place (see section 4.2.5): The place where the event happened.	1

### **Examples:**

## 4.5.5 Info

The info structure represents general information that does not fit well into other assertion structures.

## Definition:

```
<info>
  content: (text, personid)
</info>
```

# Content of info:

Element	Type/description	Level
text	stringlang structure (see section 4.2.1): This is the actual	1
	information.	
personref	personref: Pointer to the person of which this information apply.	1

# 4.5.6 Personref

The personref structure represents a link between an assertion and a person. A sequential number may be supplied. This states the sequence of assertions for a person. The number should be unique

for each person, but it is not required. The sequence of assertions with equal sequential numbers for the same person, must be regarded as not specified.

### Definition:

```
<[personref]>
attribute: (seq?)
data: ref
</[personref]>
```

Note that the name of the structure may vary.

# Content of personref:

Element	Type/description	Level
seq	int: Sequential number specifying the sequence of assertions for the	3
	referred person.	

## 4.5.7 PersonrefRole

The *personrefrole* structure is a pointer to a person that has a subordinate role in the event of which *personrefrole* is a subject.

### Definition:

```
<[personrefrole]>
    attribute: (role?)
    content: (personid)
</[personrefrole]>
```

Note that the name of the structure may vary.

## Attributes of personrefrole:

Element	Type/description	Level
role	normstringlang (see section 4.2.2): The role of this person in the	3
	related event.	

# Content of personrefrole:

Element	Type/description	Level
personid	ref: Pointer to the person that has a subordinate role in the related	3
	event.	

# **4.6** Substructures of the source structure

# 4.6.1 Repositoryref

### Definition:

```
<repositoryref>
  attributes: (ref)
  data: (callnumber?, note?)
</repositoryref>
```

# Attributes of repository:

Element Type/description L	Level	
----------------------------	-------	--

ref	int: Pointer to a repository.	3

# Data of repository:

Element	Type/description	Level
callnumber	normalizedString: The callnumber of the source in the refered	3
	repository.	
note	stringlang (see section 4.2.1): Notes concerning the specific copy of	3
	the source in the referred repository.	

## 5 GenXML levels

NOTE: THIS CHAPTER IS NOT YET UPDATED.

The features of GenXML is devided into levels to make it more easy both for the program developers and the users to understand what the capability of a genealogy program is.

The general description of each level is as follows:

- 1 The basic information of a simple genealogy program
- 2 Approximately the same information as the most commonly used parts of Gedcom 5.5
- 3 All information that an advanced genealogy program should support
- In addition to level 3 data, all data of minor importance must also be supported

#### **Definitions:**

**GenXML level X** includes all so called level X structures in addition to all level X-1 structures.

A GenXML file is said to be a **GenXML level X file** if the file does not include any structures of higher levels.

A program said to be **GenXML level X compliant**, should be able to read and write all GenXML level X files as well as files of lower levels. When importing a GenXML level X file and then exporting the same data, all data should be exported in the same structures as in the imported file.

Data loss should never occur, except when importing a level X+1 (or greater) file into a level X compliant program.

See chapter 4 for details on what level each kind of data belongs to. A summary is given below. Note that some fields are compulsory but belongs to a level higher than one. Such fields must always be exported, even if they are not imported by the same program.

### 5.1 Level 1

Level 1 is the most basic level. The following structures must at least be understood by a program in order to be called "level 1 compliant". A program that is not level 1 compliant is not GenXML compliant at all.

- The file structure with all fields.
- The header structure with all fields and substructures. Note that not all fields are compulsory.
- The eventtype structure. Note that only eventtypes of class "birth" and "death" may be supported.
- The person structure.
- The assertion structure. Note that not all substructures may be supported.
  - o Only one association structure of each class.

- Only one event structure of each class. Only "birth" and "death" events may be supported.
- Only one attribute structure of each class, and only textclass="work".
- The total structure. Note that all fields are compulsory.
- All dates may consist of only a single, exact date of the gregorian calendar without the time or alternate year specified.
- The description field of the association, personevent, attribute and coupleevent must always be exported, but may not be imported.

The substructures note, sourceref, object and todo are excluded from level 1.

### 5.2 Level 2

A program must, in order to be called "level 2 compliant", be able to read and write the following data, in addition to level 1 data:

- Additions to the header structure:
  - The language attribute.
- The source structure and all legal references to it.
- Additions to the couple structure:
  - o Additional notes (note).
- Additions to the person structure:
  - Additions to the data substructure:
    - The attribute "order", indicating the order of the substructure.
    - One alias substructure.
    - Personevent structures of the classes "baptism" and "burial".
    - When reading a file with a person with more than one alias structure or more than one association, personevent or attribute of the same class, the program must choose the first one with pref="true". If none of the said structures has this attribute, the first one must be chosen. For example if a person in a file has two personevents with class="baptism", the first with pref="false" and the second with pref="true", the second must be imported if only one of them is to be imported.
  - o Additional notes (note).
- Additions to the date structure:
  - o The modifiers "before", "after", "about" and "estimated".
  - O Dates may be described by a string.
  - o The date structure may include a period instead of an exact date.

#### 5.3 Level 3

A program must, in order to be called "level 3 compliant", be able to read and write the following data, in addition to level 2 data:

- The repository structure.
- The task structure.
- The couple structure: The number of children (nchildren).
- Additions to the person structure:
  - o Possibility of sex="unknown".
  - o Additions to the data substructure:
    - The groupref structure.
    - More than one alias substructure.
    - More than one info substructure.

- More than one association of the same class. The "class" attribute may take
  the value "other". The "relation" field may take the values "adoptive",
  "foster" or "other", as well as "biological".
- More than one personevent of the same kind. All classes of personevents must be supported, including "other".
- More than one attribute of the same class. All attribute-classes must be supported. The attribute structures may contain dates.
- o Additions to the children substructure:
  - The nchildren attribute.
- Additions to the couples substructure:
  - The nmarriages attribute.
- The object substructure.
- Dates:
  - Calendar may be "julian" or "unknown".
  - o Both "after" and "before" are possible values of the era-attribute.
  - May include alternate year.
- The pref attribute of the alias, personevent, attribute and coupleevent substructures.
- The description field of the association, personevent, attribute and coupleevent must be imported as well as exported.
- Additional note may be added to the alias, association, personevent, attribute, info and couplevent structures.
- The quality attribute of the sourceref structure.
- The lang attribute of the repository, source, couple and person structures.

#### 5.4 Level 4

A program must, in order to be called "level 4 compliant", be able to read and write the following data, in addition to level 3 data:

- The excerpt structure.
- The document structure.
- The objective structure.
- The group structure.
- Additions to the person structure:
  - o The subpersons substructure.
  - o Additions to the child substructure:
    - The order attribute.
  - Additions to the name substructure:
    - Names may be stored in a more advanced structure (see section 4.2.6).
- The datatype attribute may be added to the groupref, alias, association, personevent, attribute, info and coupleevent substructures.
- The place structure may be more advanced. It may also include a coords structure.
- The lang attribute of the note, object and place structures.
- Dates may include the time.
