Permission to copy and display the "Web Services Business Activity Framework" Specification (the "Specification", which includes WSDL and schema documents), in any medium without fee or royalty is hereby granted, provided that you include the following on ALL copies of the "Web Services Business Activity Framework" Specification that you make:

- 1. A link or URL to the "Web Services Business Activity Framework" Specification at one of the Authors' websites
- 2. The copyright notice as shown in the "Web Services Business Activity Framework" Specification.

Arjuna, BEA, Hitachi, IBM, IONA and Microsoft (collectively, the "Authors") each agree to grant you a license, under royalty-free and otherwise reasonable, non-discriminatory terms and conditions, to their respective essential patent claims that they deem necessary to implement the "Web Services Business Activity Framework" Specification.

THE "WEB SERVICES BUSINESS ACTIVITY FRAMEWORK" SPECIFICATION IS PROVIDED "AS IS," AND THE AUTHORS MAKE NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, NON-INFRINGEMENT, OR TITLE; THAT THE CONTENTS OF THE "WEB SERVICES BUSINESS ACTIVITY FRAMEWORK" SPECIFICATION ARE SUITABLE FOR ANY PURPOSE; NOR THAT THE IMPLEMENTATION OF SUCH CONTENTS WILL NOT INFRINGE ANY THIRD PARTY PATENTS, COPYRIGHTS, TRADEMARKS OR OTHER RIGHTS.

THE AUTHORS WILL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF OR RELATING TO ANY USE OR DISTRIBUTION OF THE "WEB SERVICES BUSINESS ACTIVITY FRAMEWORK" SPECIFICATION.

The name and trademarks of the Authors may NOT be used in any manner, including advertising or publicity pertaining to the "Web Services Business Activity Framework" Specification or its contents without specific, written prior permission. Title to copyright in the "Web Services Business Activity Framework" Specification will at all times remain with the Authors.

No other rights are granted by implication, estoppel or otherwise.

Abstract

This specification provides the definition of the business activity coordination type that is to be used with the extensible coordination framework described in the WS-Coordination specification. The specification defines two specific agreement coordination protocols for the business activity coordination type: BusinessAgreementWithParticipantCompletion, and BusinessAgreementWithCoordinatorCompletion. Developers can use any or all of these protocols when building applications that require consistent agreement on the outcome of long-running distributed activities.

Composable Architecture

By using the SOAP [SOAP] and WSDL [WSDL] extensibility model, SOAP-based and WSDL-based specifications are designed to work together to define a rich Web services environment. As such, WS-BusinessActivity by itself does not define all features required for a complete solution. WS-BusinessActivity is a building block used with other specifications of web services (e.g., WS-Coordination, WS-Security) and application-specific protocols that are able to accommodate a wide variety of coordination protocols related to the coordination actions of distributed applications.

Status

This specification has been developed through the WS-* Workshop process and is offered for public consideration and/or implementation.

Acknowledgments

The following individuals have provided invaluable input into the design of the WS-Transaction specification:

1 Introduction

The current set of Web service specifications [WSDL] [SOAP] defines protocols for Web service interoperability. Web services increasingly tie together a number of participants forming large distributed applications. The resulting activities may have complex structure and relationships.

The WS-Coordination specification defines an extensible framework for defining coordination types. A coordination type can have multiple coordination protocols, each intended to coordinate a different role that a Web service plays in the activity.

To establish the necessary relationships between participants, messages exchanged between participants carry a CoordinationContext. The CoordinationContext includes a Registration service Endpoint Reference of a Coordination service. Participants use that Registration service to register for one or more of the protocols supported by that activity.

To understand the protocol described in this specification, the following assumptions are made:

- The reader is familiar with the WS-Coordination [WSCOOR] specification that defines the framework for the WS-BusinessActivity coordination protocols.
- The reader is familiar with WS-Addressing [WSADDR] and WS-Policy [WSPOLICY].

This specification provides the definition of a business activity coordination type used to coordinate activities that apply business logic to handle exceptions that occur during the execution of activities of a business process. Actions are applied immediately and are permanent. Compensating actions may be invoked in the event of an error. The Business Activity specification defines protocols that enable existing business process and work flow systems to wrap their proprietary mechanisms and interoperate across trust boundaries and different vendor implementations.

Business Activities have the following characteristics:

- A business activity may consume many resources over a long duration.
- There may be a significant number of atomic transactions involved.
- Individual tasks within a business activity can be seen prior to the completion of the business activity, their results may have an impact outside of the computer system.
- Responding to a request may take a very long time. Human approval, assembly, manufacturing, or delivery may have to take place before a response can be sent.
- In the case where a business exception requires an Activity to be logically undone, abort is typically not sufficient. Exception handling mechanisms may require business logic, for example in the form of a compensation task, to reverse the effects of a previously completed task.
- Participants in a business activity may be in different domains of trust where all trust relationships are established explicitly.

These characteristics lead to a design point, with the following assumptions:

- All state transitions are reliably recorded, including application state and coordination metadata.
- All notifications are acknowledged in the protocol to ensure a consistent view of state between the coordinator and participant.
- Each notification is defined as an individual message. Transport level request/response retry and time out are not sufficient mechanisms to achieve end-to-end agreement coordination for long-running activities.

This specification leverages WS-Coordination by extending it to support business activities. It does this by adding constraints to the protocols defined in WS-Coordination and by defining its own Coordination protocols.

The constraints that Business Activity puts on WS-Coordination protocols are described in Section 2. The Business Activity Coordination protocols are defined in Section 3.

Terms introduced in this specification are explained in the body of the specification and summarized in the <u>Glossary</u>.

1.1 Model

Business Activity Coordination protocols provide the following flexibility:

• A business application may be partitioned into business activity scopes. A business activity scope is a business task consisting of a general-purpose computation carried out

as a bounded set of operations on a collection of Web services that require a mutually agreed outcome. There can be any number of hierarchical nesting levels. Nested scopes:

- Allow a business application to select which child tasks are included in the overall
 outcome processing. For example, a business application might solicit an estimate
 from a number of suppliers and choose a quote or bid based on lowest-cost.
- Allow a business application to catch an exception thrown by a child task, apply an
 exception handler, and continue processing even if something goes wrong. When a
 child completes its work, it may be associated with a compensation that is registered
 with the parent activity.
- A participant task within a business activity may specify that it is leaving a business
 activity. This provides the ability to exit a business activity and allows business
 programs to delegate processing to other scopes. In contrast to atomic transactions,
 the participant list is dynamic and a participant may exit the protocol at any time
 without waiting for the outcome of the protocol.
- It allows a participant task within a business activity to specify its outcome directly without waiting for solicitation. Such a feature is generally useful when a task fails so that the notification can be used by a business activity exception handler to modify the goals and drive processing in a timely manner.
- It allows participants in a coordinated business activity to perform "tentative" operations as a normal part of the activity. The result of such "tentative" operations may become visible before the activity is complete and may require business logic to run in the event that the operation needs to be compensated. Such a feature is critical when the joint work of a business activity requires many operations performed by independent services over a long period of time.

1.2 Notational Conventions

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC2119 [Keywords].

Namespace URIs of the general form "some-URI" represent some application-dependent or context-dependent URI as defined in RFC2396 [URI].

1.3 Namespace

The XML namespace [XML-ns] URI that MUST be used by implementations of this specification is:

http://schemas.xmlsoap.org/ws/2004/10/wsba

This URI is the business coordination type identifier.

The following namespaces are used in this document:

Prefix	Namespace
S	http://www.w3.org/2003/05/soap-envelope
wscoor	http://schemas.xmlsoap.org/ws/2004/10/wscoor
wsba	http://schemas.xmlsoap.org/ws/2004/10/wsba

If an action URI is used then the action URI MUST consist of the wsba namespace URI concatenated with the "/" character and the element name. For example:

1.4 XSD and WSDL Files

The following links hold the XML schema and the WSDL declarations defined in this document.

http://schemas.xmlsoap.org/ws/2004/10/wsba/wsba.xsd

http://schemas.xmlsoap.org/ws/2004/10/wsba/wsba.wsdl

Soap bindings for the WSDL documents defined in this specification MUST use "document" for the *style* attribute.

2 Using WS-Coordination

This section describes the Business Activity usage of WS-Coordination protocols.

2.1 CoordinationContext

A business activity uses the WS-Coordination CoordinationContext with the CoordinationType set to one of the following URIs:

http://schemas.xmlsoap.org/ws/2004/10/wsba/AtomicOutcome

http://schemas.xmlsoap.org/ws/2004/10/wsba/MixedOutcome

A coordination context may have an Expires attribute. This attribute specifies the earliest point in time at which a long-running activity may be terminated solely due to its length of operation. A participant could terminate its participation in the long running activity using the Exit protocol message.

A CoordinationContext can have additional elements for extensibility.

Due to the extensibility of WS-Coordination it is also possible to define a coordination protocol type that, in addition to specifying the agreement protocol between a coordinator and a participant, also specifies the behavior of the coordination logic. For example, it may specify that the coordinator will act in an all-or-nothing manner to determine its outcome based on the outcomes communicated by its participants, or that it will use a specific majority rule when determining its final outcome based on the outcomes of its participants.

3 Coordination Types and Protocols

Business activities support two coordination types and two protocol types. Either protocol type may be used with either coordination type.

The coordination types are atomic and mixed as identified by the following URIs:

http://schemas.xmlsoap.org/ws/2004/10/wsba/AtomicOutcome

http://schemas.xmlsoap.org/ws/2004/10/wsba/MixedOutcome

A coordinator for an AtomicOutcome coordination type must direct all participants to close or all participants to compensate. A coordinator for a MixedOutcome coordination type may direct each individual participant to close or compensate. All coordinators MUST implement the AtomicOutcome coordination type. Any coordinator MAY implement the MixedOutcome coordination type.

The Coordination protocols for business activities are summarized below with names relative to the wsba base name:

- **BusinessAgreementWithParticipantCompletion**: A participant registers for this protocol with its coordinator, so that its coordinator can manage it. A participant must know when it has completed all work for a business activity.
- BusinessAgreementWithCoordinatorCompletion: A participant registers for this protocol with its coordinator, so that its coordinator can manage it. A participant relies on its coordinator to tell it when it has received all requests to perform work within the business activity.

3.1 BusinessAgreementWithParticipantCompletion Protocol

The state diagram in Figure 1 specifies the behavior of the protocol between a coordinator and a participant. The agreement coordination state reflects what each participant knows of their relationship at a given point in time. As messages take time to be delivered, the views of the coordinator and a participant may temporarily differ. Omitted are details such as resending of messages or the exchange of error messages due to protocol error.

Participants register for this protocol using the following protocol identifier:

http://schemas.xmlsoap.org/ws/2004/10/wsba/ParticipantCompletion

The coordinator accepts:

Completed

Upon receipt of this notification, the coordinator knows that the participant has completed all processing related to the protocol instance. For the next protocol message the coordinator should send a Close or Compensate notification to indicate the final outcome of the protocol instance.

Fault

Upon receipt of this notification, the coordinator knows that the participant has failed from the active or compensating state. For the next protocol message the coordinator should send a Faulted notification. This notification carries a QName defined in schema indicating the cause of the fault.

Compensated

Upon receipt of this notification, the coordinator knows that the participant has recorded a compensation request for a protocol.

Closed

Upon receipt of this notification, the coordinator knows that the participant has finalized successfully.

Canceled

Upon receipt of this notification, the coordinator knows that the participant has finalized successfully processing the Cancel notification.

Exit

Upon receipt of this notification, the coordinator knows that the participant will no longer participate in the business activity. For the next protocol message the coordinator should send an Exited notification.

The participant accepts:

Close

Upon receipt of this notification, the participant knows the protocol instance is to complete successfully. For the next protocol message the participant should send a Closed notification to end the protocol instance.

Cancel

Upon receipt of this notification, the participant knows that the work being done has to be canceled. For the next protocol message the participant should send a Canceled notification to end the protocol instance.

Compensate

Upon receipt of this notification, the participant knows that the work being done should be compensated. For the next protocol message the participant should send a Compensated notification to end the protocol instance.

Faulted

Upon receipt of this notification, the participant knows that the coordinator is aware of a fault and no further actions are required of the participant.

Exited

Upon receipt of this notification, the participant knows that the coordinator is aware the participant will no longer participate in the activity.

Both the coordinator and participant accept:

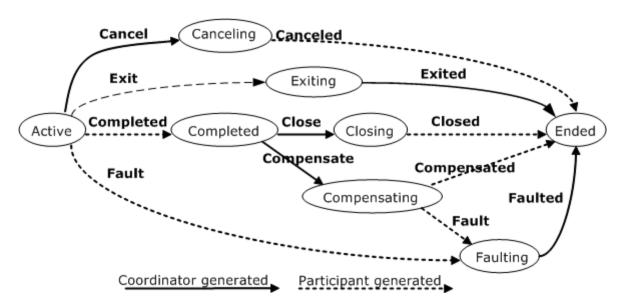

GetStatus

This message requests the current state of a coordinator or participant. In response the coordinator or participant returns a Status message containing a QName indicating which row of the state table [Appendix A: State Tables for the Agreement Protocols] the coordinator or participant is currently in. GetStatus never provokes a state change.

Status

Upon receipt of this message the target service returns a QName defined in schema indicating the current state of the coordinator or participant. For example, if a participant is in the closing state as indicated by the state table, it would return wsba:Closing.

Figure 1: BusinessAgreementWithParticipantCompletion abstract state diagram.

The coordinator can enter a condition in which it has sent a protocol message and it receives a protocol message from the participant that is consistent with the former state, not the current state. In this case, it is the responsibility of the coordinator to revert to the prior state, accept the notification from the participant, and continue the protocol from that

point. If the participant detects this condition, it must discard the inconsistent protocol message from the coordinator.

A party should be prepared to receive duplicate notifications. If a duplicate message is received it should be treated as specified in the state tables described in this document.

3.2 BusinessAgreementWithCoordinatorCompletion Protocol

The BusinessAgreementWithCoordinatorCompletion protocol is the same as the BusinessAgreementWithParticipantCompletion protocol, except that a participant relies on its coordinator to tell it when it has received all requests to do work within the business activity.

Participants register for this protocol using the following protocol identifier:

http://schemas.xmlsoap.org/ws/2004/10/wsba/CoordinatorCompletion

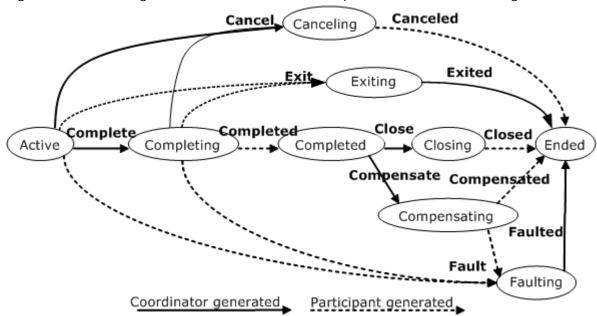

In addition to the notifications in Section 3.1, Business agreement with coordinator completion supports the following:

The participant accepts:

Complete

Upon receipt of this notification the participant knows that it will receive no new requests for work within the business activity. It should complete application processing and transmit the Completed notification.

Figure 2: BusinessAgreementWithCoordinatorCompletion abstract state diagram.

4. BA Policy Assertions

WS-Policy Framework [WS-Policy] and WS-Policy Attachment [WSPOLICYATTACH] collectively define a framework, model and grammar for expressing the capabilities, requirements, and general characteristics of entities in an XML Web services-based system. To enable a web service to describe business activity-related capabilities and requirements of a service and its operations, this specification defines a pair of Business Agreement policy assertions that leverage the WS-Policy framework.

4.1 Assertion Models

The BA policy assertions are provided by a web service to qualify the business activity-related processing of messages associated with the particular operation to which the assertions are scoped. The BA policy assertions indicate:

 whether the sender of an input message MAY, MUST or SHOULD NOT include an AtomicOutcome coordination context flowed with the message. The coordination type of such a context MUST be the following:

```
http://schemas.xmlsoap.org/ws/2004/10/wsba/AtomicOutcome
```

whether the sender of an input message MAY, MUST or SHOULD NOT include a MixedOutcome coordination context flowed with the message. The coordination type of such a context MUST be the following:

http://schemas.xmlsoap.org/ws/2004/10/wsba/MixedOutcome

4.2 Normative Outlines

The normative outlines for the BA policy assertions are:

The following describes additional, normative constraints on the outline listed above:

/wsba: BAAtomicOutcomeAssertion

A policy assertion that specifies that the sender of an input message MUST include a coordination context for a business activity with AtomicOutcome coordination type flowed with the message.

/wsba: BAAtomicOutcomeAssertion/@wsp:Optional="true"

Per WS-Policy [WS-Policy], this is compact notation for two policy alternatives, one with and one without the assertion. Presence of both policy alternatives indicates that the behavior indicated by the assertion is optional, such that an AtomicOutcome coordination context MAY be flowed inside an input message. The absence of the assertion is interpreted to mean that an AtomicOutcome coordination context SHOULD NOT be flowed inside an input message.

```
<wsba:BAMixedOutcomeAssertion [wsp:Optional="true"]? ... >
    ...
</wsba:BAMixedOutcomeAssertion>
```

The following describes additional, normative constraints on the outline listed above:

/wsba: BAMixedOutcomeAssertion

A policy assertion that specifies that the sender of an input message MUST include a coordination context for a business activity with MixedOutcome coordination type flowed with the message.

/wsba: BAMixedOutcomeAssertion/@wsp:Optional="true"

Per WS-Policy [WS-Policy], this is compact notation for two policy alternatives, one with and one without the assertion. Presence of both policy alternatives indicates that the behavior indicated by the assertion is optional, such that a MixedOutcome coordination context MAY be flowed inside an input message. The absence of the assertion is interpreted to mean that an MixedOutcome coordination context SHOULD NOT be flowed inside an input message.

4.3 Assertion Attachment

Because the BA policy assertions indicate business activity-related behavior for a single operation, the assertions have Operation Policy Subject.

WS-PolicyAttachment [WSPOLICYATTACH] defines two [WSDL] policy attachment points with Operation Policy Subject:

- wsdl:portType/wsdl:operation A policy expression containing a BA policy assertion MUST NOT be attached to a wsdl:portType; the BA policy assertions specify a concrete behavior whereas the wsdl:portType is an abstract construct.
- wsdl:binding/wsdl:operation A policy expression containing a BA policy assertion SHOULD be attached to a wsdl:binding.

4.4 Assertion Example

An example use of the BA policy assertion follows:

```
(01)
      <wsdl:definitions</pre>
(02)
          targetNamespace="hotel.example.com"
(03)
          xmlns:tns="hotel.example.com"
(04)
          xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
(05)
          xmlns:wsp="http://schemas.xmlsoap.org/ws/2004/09/policy"
(06)
          xmlns:wsat="http://schemas.xmlsoap.org/ws/2004/10/wsba"
(07)
          xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-
                       wssecurity-utility-1.0.xsd" >
(80)
(09)
        <wsp:Policy wsu:Id="BAAtomicPolicy" >
(10)
          <wsba:BAAtomicOutcomeAssertion/>
          <!-- omitted assertions -->
(11)
(12)
        </wsp:Policy>
        <!-- omitted elements -->
(13)
(14)
        <wsdl:binding name="HotelBinding" type="tns:HotelPortType" >
          <!-- omitted elements -->
(15)
          <wsdl:operation name="ReserveRoom" >
(16)
            <wsp:PolicyReference URI="#BAAtomicPolicy"</pre>
(17)
(18)
                                             wsdl:required="true" />
            <!-- omitted elements -->
(19)
(20)
          </wsdl:operation>
        </wsdl:binding>
(21)
```

Lines (9-12) are a policy expression that includes a BA policy assertion (Line 10) to indicate that a coordination context for a business activity with an AtomicOutcome, expressed in WS-Coordination [WS-Coordination], format MUST be used.

Lines (16-20) are a WSDL [WSDL 1.1] binding. Line (17) indicates that the policy in Lines (9-12) applies to this binding, specifically indicating that a coordination context for a business activity with an AtomicOutcome MUST flow inside "ReserveRoom" messages.

5 Security Considerations

It is strongly RECOMMENDED that the communication between services be secured using the mechanisms described in WS-Security [WSSec]. In order to properly secure messages, the body and all relevant headers need to be included in the signature. Specifically, the <wscoor:CoordinationContext> header needs to be signed with the body and other key message headers in order to "bind" the two together.

In the event that a participant communicates frequently with a coordinator, it is RECOMMENDED that a security context be established using the mechanisms described in WS-Trust [WSTrust] and WS-SecureConversation [WSSecConv] allowing for potentially more efficient means of authentication.

It is common for communication with coordinators to exchange multiple messages. As a result, the usage profile is such that it is susceptible to key attacks. For this reason it is strongly RECOMMENDED that the keys be changed frequently. This "re-keying" can be effected a number of ways. The following list outlines four common techniques:

- Attaching a nonce to each message and using it in a derived key function with the shared secret
- Using a derived key sequence and switch "generations"
- Closing and re-establishing a security context (not possible for delegated keys)
- Exchanging new secrets between the parties (not possible for delegated keys)

It should be noted that the mechanisms listed above are independent of the SCT and secret returned when the coordination context is created. That is, the keys used to secure the channel may be independent of the key used to prove the right to register with the activity.

The security context MAY be re-established using the mechanisms described in WS-Trust [WSTrust] and WS-SecureConversation [WSSecConv]. Similarly, secrets can be exchanged using the mechanisms described in WS-Trust. Note, however, that the current shared secret SHOULD NOT be used to encrypt the new shared secret. Derived keys, the preferred solution from this list, can be specified using the mechanisms described in WS-SecureConversation.

The following list summarizes common classes of attacks that apply to this protocol and identifies the mechanism to prevent/mitigate the attacks:

- Message alteration Alteration is prevented by including signatures of the message information using WS-Security [WSSec].
- Message disclosure Confidentiality is preserved by encrypting sensitive data using WS-Security.

- **Key integrity** Key integrity is maintained by using the strongest algorithms possible (by comparing secured policies see WS-Policy [WSPOLICY] and WS-SecurityPolicy [WSSecPolicy]).
- Authentication Authentication is established using the mechanisms described in WS-Security and WS-Trust [WSTrust]. Each message is authenticated using the mechanisms described in WS-Security [WSSec].
- **Accountability** Accountability is a function of the type of and string of the key and algorithms being used. In many cases, a strong symmetric key provides sufficient accountability. However, in some environments, strong PKI signatures are required.
- Availability Many services are subject to a variety of availability attacks. Replay is a
 common attack and it is RECOMMENDED that this be addressed as described in the next
 bullet. Other attacks, such as network-level denial of service attacks are harder to avoid
 and are outside the scope of this specification. That said, care should be taken to
 ensure that minimal processing be performed prior to any authenticating sequences.
- **Replay** Messages may be replayed for a variety of reasons. To detect and eliminate this attack, mechanisms should be used to identify replayed messages such as the timestamp/nonce outlined in WS-Security [WSSec]. Alternatively, and optionally, other technologies, such as sequencing, can also be used to prevent replay of application messages.

6 Interoperability Considerations

In order for two parties to communicate, both parties will need to agree on the protocols provided. This specification facilitates this agreement and thus interoperability.

7 Glossary

Cancel – Back out of a business activity.

Close – Terminate a business activity with a favorable outcome.

Compensate – A message to a Completed participant from a coordinator to execute its compensation. This message is part of both the

BusinessAgreementWithParticipantCompletion and

 $Business Agreement With Coordinator Completion\ protocols.$

Complete – A message to a participant from a coordinator telling it that it has been given all of the work for that business activity. This message is part of the BusinessAgreementWithCoordinatorCompletion protocol.

Completed – A message from a participant telling a coordinator that the participant has successfully executed everything asked of it and needs to continue participating in the protocol. This message is part of both the BusinessAgreementWithParticipantCompletion and BusinessAgreementWithCoordinatorCompletion protocols.

Exit – A message from a participant telling a coordinator that the participant does not need to continue participating in the protocol. This message is part of both the BusinessAgreementWithParticipantCompletion and BusinessAgreementWithCoordinatorCompletion protocols.

Fault – A message from a participant telling a coordinator that the participant could not execute successfully.

BusinessAgreementWithParticipantCompletion protocol – A business activity coordination protocol that supports long-lived business processes and allows business logic

to handle business logic exceptions. A participant in this protocol must know when it has completed with its tasks in a business activity.

BusinessAgreementWithCoordinatorCompletion protocol – A business activity coordination protocol that supports long-lived business processes and allows business logic to handle business logic exceptions. A participant in this protocol relies on its coordinator to tell it when it has received all requests to do work within a business activity.

Scope – A business activity instance. A scope integrates coordinator and application logic. A web services application can be partitioned into a hierarchy of scopes, where the application understands the relationship between the parent scope and its child scopes.

Appendix A: State Tables for the Agreement Protocols

The following state tables show state transitions that occur in the *receiver* when a protocol message is received or in the *sender* when a protocol message is sent. Each table uses the following convention:

Action to take next state

where the next state refers to the next agreement protocol state. An Action of *Invalid State* means the sent or received protocol message cannot occur in the current state.

The following rules need to be applied when reading the state tables in this document:

- For the period of time that a protocol message is in transit the sender and recipient states will be different.
 - The sender of a protocol message transitions to the "next state" when the message is first sent
 - The recipient of a protocol message transitions to the "next state" when the message is first received.
- As described earlier in this document, if the coordinator receives a protocol message
 from the participant that is consistent with the former state of the coordinator then
 the coordinator reverts to its prior state, accepts the notification from the
 participant, and continues the protocol from that point.

The GetStatus and Status protocol messages are not included in the tables as these never result in a change of state.

A.1 Participant view of BusinessAgreementWithParticipantCompletion

Business	BusinessAgreementWithParticipantCompletion protocol
